Selection of rod end and spherical bearing size

The selection and determination of spherical bearing and rod end sizes in Schedule K must be based on the specified load capacity, applied loads and requirements for useful life and operating safety.

The load ratings specified in the tables serve as definitive characteristic and arithmetic values for the load capacity of the spherical bearings an rod ends.

Load ratings from different manufacturers cannot always be compared with each other, since no standardised load rating definition exists for spherical bearings an rod ends.

The following conditions are used as a basis for the load ratings of Askubal heavy-duty spherical bearings and rod ends:

Static load capacity C_0 (plain bearings)

The static load capacity C_0 is the radially acting static load which does not cause any permanent deformation of the components when the spherical bearing or rod end is stationary, i.e. the load condition without pivoting, swivelling or tilting movements. It is also a precondition here that the operating temperature must be in the normal room temperature range and the surrounding components must possess sufficient stability.

The values specified in the tables are determined by static tension tests on a representative number of series components at 20°C normal room temperature. The static load capacity may vary by lower or higher temperature according to the material.

In the case of all Askubal rod ends with plain bearings, the static load rating refers to the maximum permissible static load of the rod end housing in tensile direction up to which no permanent deformation occurs at the weakest housing cross-section.

Static load capacity C_0 (roller bearings)

In the case of Askurol rod ends with roller bearings, the static load rating is the load at which the overall permanent deformation of rolling elements and raceways is max. 0.0001 of the rolling element diameter.

Dynamic load capacity C (plain bearings)

Dynamic load ratings serve as arithmetic values for calculation of the service life of dynamically-loaded spherical bearings and rod ends. The values themselves do not provide any information about the effective dynamic load capacity of the spherical bearing or rod end. To obtain this information, it is necessary to take into account the additional influencing factors such as load type, swivel or tilt angle, speed characteristic, max. permitted bearing clearance, max. permitted bearing friction, lubrication conditions and temperature, etc.

Dynamic load capacities depend on the definition used to calculate them. Comparison of values is not always possible owing to the different definitions used by various manufacturers, and because the load capacities are often determined under completely different test conditions.

Dynamic load capacity C (roller bearings)

In the case of Askurol rod ends with roller bearings, the dynamic load capacity is the load at which 90% of a large quantity of identical rod ends reach 1 million revolutions before they fail owing to fatigue of the rolling surfaces.

Operating temperature

All Askubal spherical bearings and rod ends can be used without restriction in an operating temperature range of between -10 °C bis +80 °C.

Increase of operating temperature occurs a decrease of load capacity of the rod end housing and the bearing therefore the useful life will be reduced too.

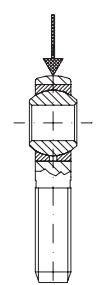

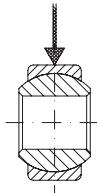

Rod end selection

When choosing a rod end, it is essential to know whether the load is to be static or dynamic. In the case of static loading (load without pivot, swivel or tilt movements) the maximum static load capacity corresponds to the static load rating C_0 specified in the tables. No permanent deformation of the rod end housing occurs up to this load.

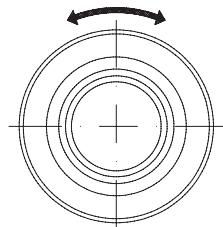

When choosing a rod end be sure that the real load is always explicitly less than the maximum load capacity of the rod end.

Load direction

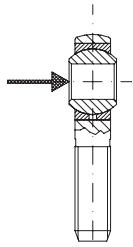

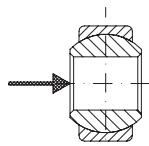

The load is of prime importance in the selection of bearing size, however the load direction is also important.
A differentiation is made between the following load directions.

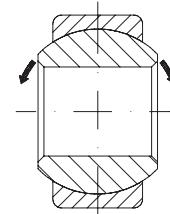

Radial load

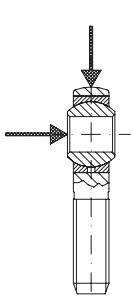

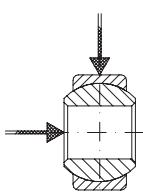

Swivelling
(oscillating)

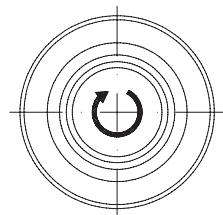

Axial load

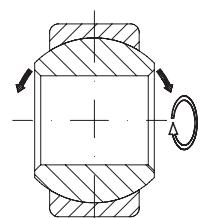

Tilting

Combined load

Full pivot
(rotating)

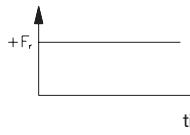

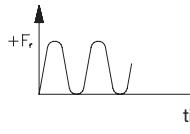

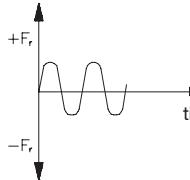

Tilting and swivelling
or rotating

Bearing movement

A differentiation is made between the following bearing movements in spherical bearings:

Housing load capacity

Depending on the load type, the following load factors must be taken into account for the permitted max. radial housing load capacity $F_{r\ perm}$:

Load type		Load factor S_B	Load factor S_K
	constant	1	0.7
	pulsating	0.333	0.7
	alternating	0.166	0.7

The load factor S_K is valid for rod ends with male thread and lubricating hole or lubricating nipple.

The named load factors should be used to value the limited load capacity. Load factors for shock load, also caused by increasing the bearing clearance or by an additional load due to simultaneous swivel movements are not included. The load factor S_K , which considers the weakening of the unit can only be a rough reference value. In extreme operating conditions specially in cases where the life and safety of individuals is placed at risk, practice-oriented tests must be verified.

The permitted radial housing load capacity $F_{r\ perm}$ is reduced as follows:

$$F_{r\ perm} [\text{kN}] = \text{stat. load } C_0 [\text{kN}] \cdot S_B \cdot (S_K)$$

Note: Caution! Special requirements must be fulfilled for use of these components in aircraft. For this reason, we can accept no product liability for applications of this kind.

Spherical bearing load capacity

A mounted spherical bearing has a considerably higher static load capacity than a rod end housing, as can be seen in a comparison of the static load ratings for rod ends and for the equivalent spherical bearings.

Dynamic load

Basically an exact calculation of useful life is not possible, because of the conditions of use and the factors of influence which are often very hard to collect.

Therefore experiences of already performed and comparable applications are highly important. To decide the size of bearing you further have to consider the following criteria:

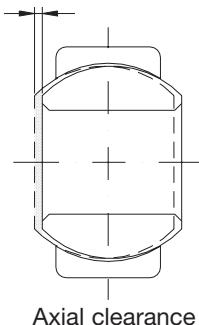

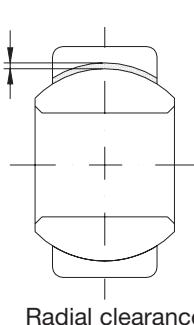

- the load capacity of the housing
 - the selection of mating materials for the spherical bearing
- We will best possibly support your selection. Please ask us for help.

Bearing clearance

Bearing clearance is defined as the radial and axial freedom of motion of the inner ring (see illustration). The radial clearance given in the tables is based on a radial measuring load of $\pm 100\text{N}$.

Reduced or enlarged bearing clearances (C3 or C2) are available on request.

In plain bearings the axial clearance could be several times higher than the radial clearance.

Radial clearance

*) on request

In antifriction bearings the axial clearance could be several times higher than the radial clearance.

Tilt angle limitation

For all Askubal spherical bearings and Askurol rods ends, the maximum tilt angle specified in the tables must not be exceeded while mounting or during operation, otherwise the bearing or washers and cover washers may be damaged. The assembly must be constructed so that the rod end or spherical bearing is effectively prevented from moving further than the given angle (Fig. a). At the same time, however, no major forces may be applied to the housing. It is also important to ensure that there is always sufficient space available for the seal (particularly with 2RS models), in order to prevent contact with the surrounding components (Fig. b).

Mounting instructions

Installation

All Askubal spherical bearings and rod ends are very high precision, ready-to-fit bearing elements. For this reason, they must be stored carefully and installed correctly. It is important to comply with the following points:

1. The spherical bearings and rod ends must be kept in their original packaging until shortly before their installation, so that they continue to be effectively preserved for as long as possible. Ensure during the installation process that foreign particles are on no account allowed to enter the outer ring of the bearing.
2. The forces required for installation and removal should on no account be transmitted from the spherical form to the bearing shells or raceways of the bearing outer ring.
3. In order for the spherical bearings to run smoothly, the sliding movement must take place between the sliding faces of the bearing inner ring and outer ring. Sliding movements on the shaft or in the housing cause damage and premature failure. For this reason, it is essential for there to be an interference fit between the bearing housing and bearing outer ring and between the bearing inner ring and the connection shaft. This can be achieved by using tight fits and with axial tensioning of the bearing rings. However, the consequence of using tight fits is an alteration in the bearing clearance. Too high interference between the housing and the bearing outer ring causes contraction of the outer ring. Too high interference between the connection shaft and the inner ring causes the inner ring to expand.

Maintenance and lubrication

The useful life of all spherical bearings and rod ends with metallic mating materials is greatly dependent on regular lubrication. A one-off initial grease filling is only adequate if operating loads are very low.

The effectiveness of lubrication is mainly dependent on the load, type of load (constant, pulsating or alternating), the swivel angle and sliding speed.

Numerous tests in our ASK laboratory have shown that small swivel angles and both very low and very high sliding speeds have an unfavourable effect on the formation of a film of lubricant. A load which acts in one direction only is also unfavourable compared to an alternating load.

To ensure optimum and even distribution of the lubricant, initial lubrication and subsequent lubrication should be carried out with the spherical bearing or rod end in an unloaded condition.

Note

In order to avoid incompatibility of various lubricants that may be used by ASK and the customer, spherical bearings and rod ends are supplied only with an anticorrosive coating. For this reason, spherical bearings and rod ends which need maintenance should be given initial lubrication before commissioning or directly after installation. We recommend carrying out initial lubrication after a running-in time of approx. 1 hour. Whenever this lubrication is carried out, the bearing must be in an unloaded condition, so that the lubricant can spread without obstruction. Lubrication should continue until the lubricant emerges between the bearing outer ring and the inner ring. For rod ends with a female thread, it is also advisable to fill the space in the shank thread with lubricant up to the threaded connection journal before installation. This reduces the amount of work involved in lubricating with the lubricating nipple.

Mating materials steel on high-duty bronze

We recommend using corrosion inhibiting, pressure-resistant lithium-base greases or lithium complex metallic soap greases for lubrication of this material combination. The operating temperature range should be between -20°C and +110°C. It is possible to reduce friction and increase the useful life of components which are used under load conditions in the upper limit range by using solid lubricants. These are available on request.

Mating materials steel on PTFE

This material combination is distinguished by its low friction. The antifriction film is made of a material which makes lubrication unnecessary, so that maintenance-free operation is possible.

Askubal antifriction bearings

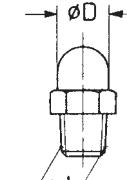

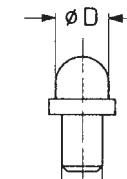

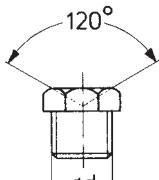

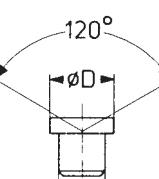

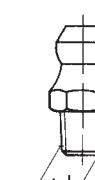

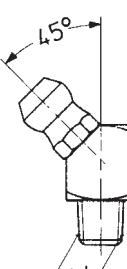

Ball bearings: These rod ends are given permanent lubrication with a lithium soap grease. Subsequent lubrication is not required. There is, however, a version available for a swivel angle of <5° which does require subsequent lubrication.

Roller bearings: These rod ends are given initial lubrication with a lithium soap grease. If they are used in heavy operating conditions, these rod ends can be relubricated through the fitted lubricating nipples.

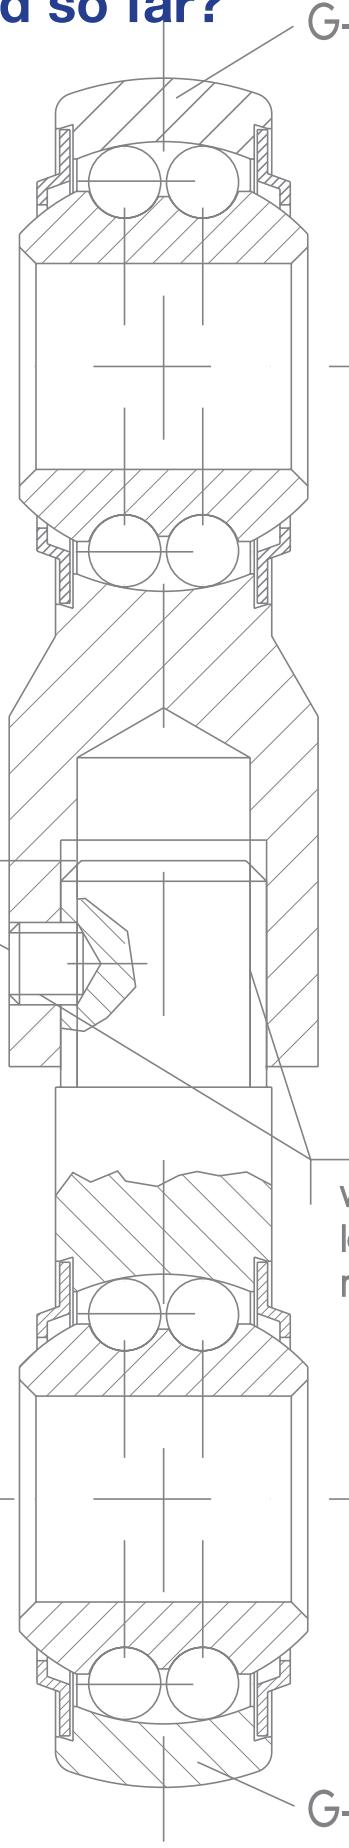

Please note, that the use of a non standard lubricating nipple (DIN 3405 shape D) causes a cross sectional variation for

housings with male thread which means a reduction of the static load capacity C_0 .

dimension series K

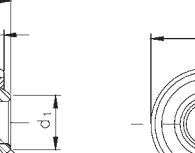

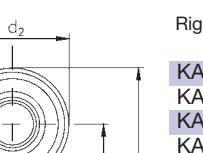

Inner ring:	Antifriction bearing steel, hardened, ground and polished.
Outer ring:	Brass lined with an antifriction film, consisting of PTFE, cold formed around inner ring.
Housing:	Sizes 5 to 12 free-cutting steel, sizes 14 to 50 tempering steel (standardised), all sizes galvanized and chromatised. The spherical bearing ia pressed into the housing and caulked at both sides.

Mating materials:
Stainless steel on high-duty bronze
Maintenance required
Stainless steel
**DIN ISO 12240-4
dimension series K**
Inner ring:

Stainless steel, hardened, ground and polished.

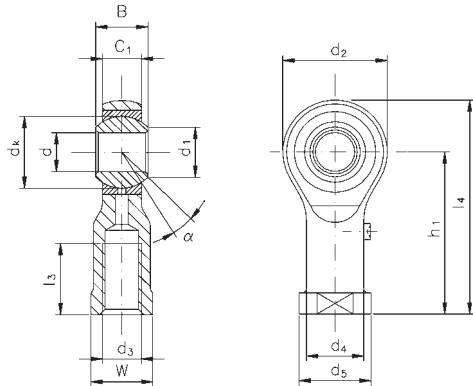

Outer ring:

Swaged around the inner ring, sliding face made of high-duty bronze. Lubricant is distributed via the lubricating groove in the outer ring.

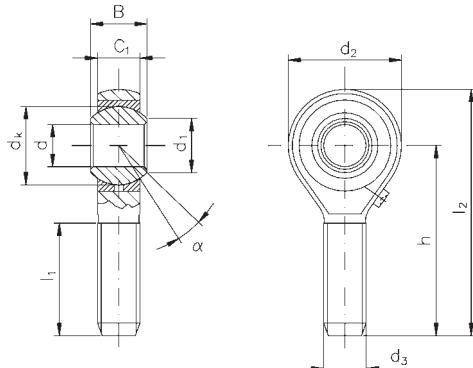

Housing:

Stainless steel. The spherical bearing is pressed into the housing and caulked at both sides.

Lubrication nipple: Size 5 without lubrication nipple. Sizes 6 to 30 lubricating nipple DIN 3405, shape D. Further lubricating nipple shapes available on request.

Mating materials:
Steel on high-duty bronze
Maintenance required

Pneumatic

Special version for
pneumatic cylinder

Inner ring: Antrifiction bearing steel, hardened, ground and polished.

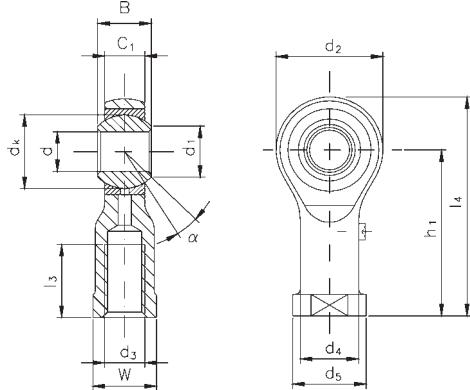

Outer ring: Swaged around the inner ring, sliding face made of high-duty bronze. Lubricant is distributed via the lubricating groove in the outer ring.

Housing: Sizes 5 to 12 free-cutting steel, sizes 16 to 50 tempering steel (standardised), all sizes galvanized and chromatised. The spherical bearing is pressed into the housing and caulked at both sides.

Lubrication nipple: Size 5 without lubricating nipple, sizes 6 to 50 lubricating nipple DIN 3405, shape D, further lubricating nipple shapes available on request.

Ball bearing

Mounting sizes acc.
to DIN ISO 12240-4
dimension series K

Inner ring:

Antifriction bearing steel, hardened, raceway precision ground.

Housing:

To size 12 made of free-cutting steel with bearing outer ring pressed into housing, raceway precision ground. Size 16 made of case hardening steel, raceway hardened and precision ground.

Rolling element:

Balls made from through-hardened, antifriction bearing steel.

Cover washer:

Aluminium sheet, caulked in housing.

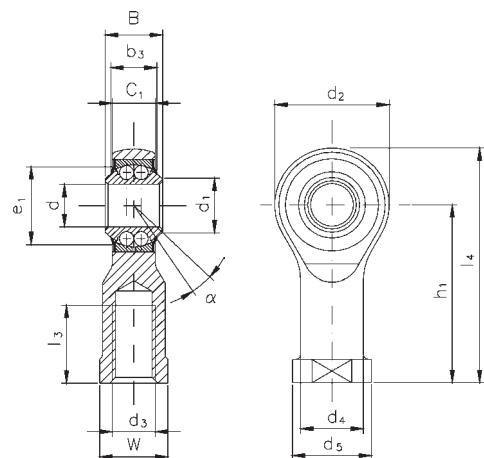

Lubrication:

The rod ends are given lifetime lubrication. There is, however, a version available on request for a swivel angle of < 5° which requires subsequent lubrication.

Note:

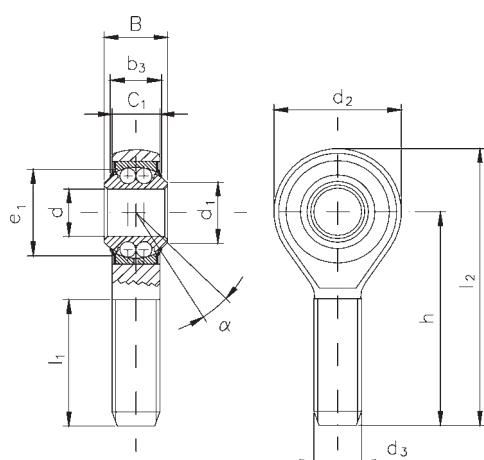

With these rod ends, it is important to ensure that the tilt angle specified in the table is not exceeded, either while mounting or during operation, otherwise the cover washers may be damaged.

KUA 16	KUAL 16	16	M16	21	15.00	18.0	19.3	43

Max. permissible speed:

This is affected by the bearing load, the bearing clearance, the lubricant and heat output and input. The maximum permissible speed given in the tables applies for a purely radial load, normal bearing clearance tolerance, no external heat, an operating temperature which is not above the limit, and a low and absolutely shock-free load.

Note:

With these rod ends, it is important to ensure that the tilt angle specified in the table is not exceeded, either while mounting or during operation, otherwise the sealing washers may be damaged.

Max. permissible speed:

This is affected by the bearing load, the bearing clearance, the lubricant and heat output and input. The maximum permissible speed given in the tables applies for a purely radial load, normal bearing clearance tolerance, no external heat, an operating temperature which is not above the limit, and a low and absolutely shock-free load.

Special versions:

available on request

Steel on high-duty bronze
Maintenance required

RS

Special version
 adjustable clearance
 2RS sealing

Inner ring: Antifriction bearing steel, hardened, ground and polished.

Outer ring: Swaged around the inner ring, sliding face made of high-duty bronze. Lubricant is distributed via the lubrication groove in the outer ring.

rubber bellows: Synthetic rubber.

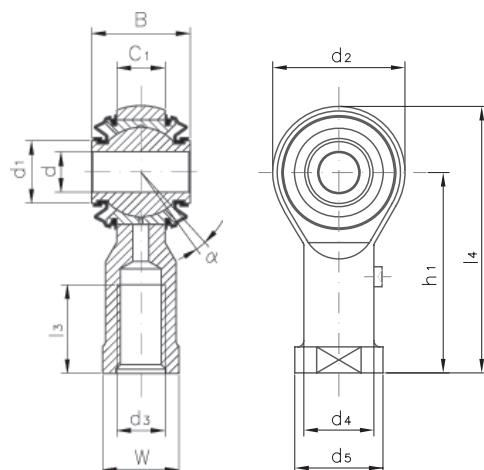

Housing: Sizes 8 to 12 free-cutting steel, sizes 14 to 30 tempering steel (standardised), all sizes galvanized and chromatised.

Lubricating nipple: DIN 3405, shape D, further lubricating nipple shapes available on request.

Tolerances: To DIN ISO 12240-4, schedule K, except: $d = H10$, $B = +0.3$

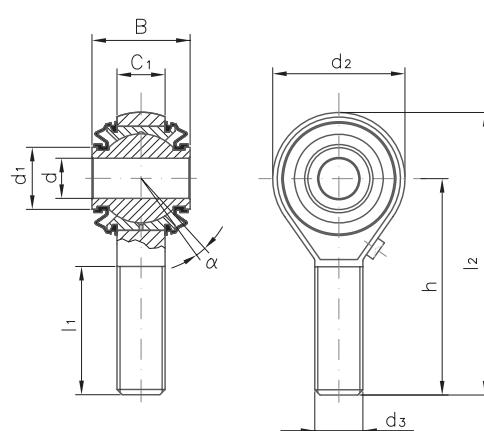

Note: With these rod ends, it is important to ensure that the tilt angle specified in the table is not exceeded, either while mounting or during operation, otherwise the rubber bellows may be damaged. Replacement for previous 2RS-version. Available starting midyear 2008.

Type S

Special version

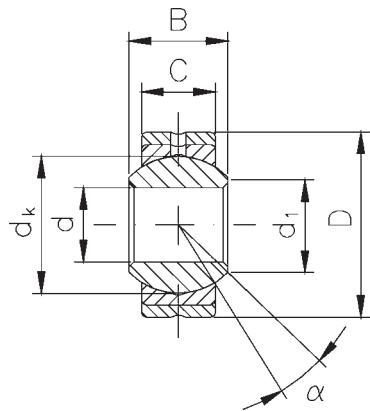

Inner ring: Antifriction bearing steel, hardened, ground and polished.

Outer ring: Swaged around the inner ring, outside diameter ground. Sliding face made of high-duty bronze. Lubricant is distributed via the lubricating groove in the outer ring.

Outer case: Free-cutting steel, outside diameter ground. Spherical bearing is pressed into the outer case and secured at both sides against axial movement. However the two outer rings should be axial supported at mounting.

Lubrication: The lubricant enters the lubricating groove through a cross hole in the outer case.

Special versions: are available on request e.g.:
 - Sliding face of inner ring 5 mm to 10 mm hard chromium plated.
 - Outer case made of stainless steel.

Mating materials:

Stainless steel on

heavy-duty bronze

Maintenance required

Stainless steel

Special version type S

Inner ring:

Stainless steel, hardened, ground and polished.

Outer ring:

Swaged around the inner ring, outside diameter ground. Sliding face made of high-duty bronze. Lubricant is distributed via the lubricating groove in the outer ring.

Outer case:

Stainless steel, outside diameter ground. Spherical bearing is pressed into the outer case and secured at both sides against axial movement.

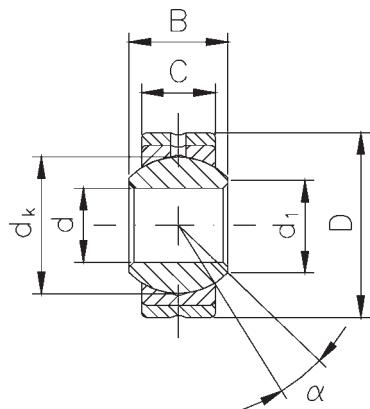

Lubrication:

The lubricant enters the lubricating groove through a cross hole in the outer case.

Special versions:

- **Version -R:**
as standard, but inner ring hard chromium plated.

Further versions are available on request.

RS

Special version
 2RS sealing

Inner ring: Antifriction bearing steel, hardened, ground and polished.

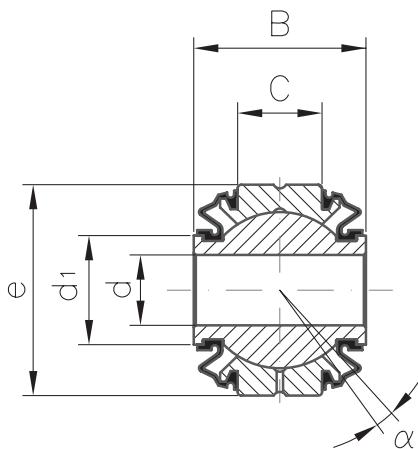

Outer ring: Swaged around the inner ring, sliding face made of high-duty bronze. Lubricant is distributed via the lubrication groove in the outer ring.

Rubber bellows: Synthetic rubber.

Lubrication: The lubricant enters the lubricating groove through a cross hole in the outer ring.

Tolerances: To DIN ISO 12240-1, schedule K, except: d = H10, B = +-0.3

Note: With these rod ends, it is important to ensure that the tilt angle specified in the table is not exceeded, either while mounting or during operation, otherwise the rubber bellows may be damaged. Replacement for previous 2RS-version. Available starting midyear 2008.

Mating materials:
Steel on steel
Maintenance required
HO2RS

 DIN ISO 12240-1
 dimension series W
 2RS-sealing

Inner ring: Antifriction bearing steel, hardened, ground, phosphated.

Outer ring: Antifriction bearing steel, hardened, ground, phosphated. Outer ring is split for assembly of inner ring.

Lubrication: Lubrication groove and lubrication hole, relubrication is also possible through the inner bore.

Radial clearance: see technical basics, table spherical bearings dimension series E, mating materials steel on steel.
